Histogram of regional_node_positive

see the correlation between regional.node.examined and regional.node.positive

```
pairs_data <- data[, c("regional_node_examined", "regional_node_positive")]  
  
pairs(pairs_data, main = "Pairs Plot: Regional Node Examined vs Regional Node Positive",  
      pch = 21, bg = "lightblue")
```

Pairs Plot: Regional Node Examined vs Regional Node Positive

Linear Trend: There appears to be a positive association between `Regional.Node.Examined` and `Regional.Node.Positive`. As the number of nodes examined increases, the number of positive nodes also tends to increase. However, the relationship is not perfectly linear; there is noticeable spread in the points.

High Variability: There is significant variability in `Regional.Node.Positive` values for a given range of `Regional.Node.Examined`. This suggests that other factors might influence the number of positive nodes beyond the number of examined nodes.

Outliers: A few observations stand out as potential outliers, particularly where `Regional.Node.Examined` is high, but the number of `Regional.Node.Positive` remains low (or vice versa). These outliers could be influential points worth further investigation.

introduce a new variable proportion

From the result above, we choose model 4 as our best model. Because it includes all predictors (age, race, t_stage, n_stage, tumor_size, estrogen_status, progesterone_status, node_proportion, and survival_months). And it has the lowest residual deviance and AIC value among all models (Residual Deviance = 2294.8, AIC = 2314.8). While the significant predictors include age, t_stage, n_stage, progesterone_status, node_proportion, and survival_months, with p-values below 0.05. It offers the most comprehensive evaluation and balances the trade-off between simplicity and explanatory power. #Model Validation

```
# Split data into training and test sets
set.seed(123)
train_indices <- sample(seq_len(nrow(data)), size = 0.7 * nrow(data))
train_data <- data[train_indices, ]
test_data <- data[-train_indices, ]

# Fit the selected model (Model 4) on training data
model4 <- glm(status ~ age + race + t_stage + n_stage + tumor_size +
```

```

        estrogen_status + progesterone_status + node_proportion + survival_months,
        data = train_data, family = binomial)

# Predict probabilities on test data

```

##Validation result: Accuracy: 88.17% (with 95% CI of 86.2% - 89.94%) High accuracy indicates good overall model performance.

Sensitivity: 39.90% Indicates the model's ability to correctly identify the positive class (Dead cases). While sensitivity is moderate, this is often a tradeoff in medical or survival models.

Specificity: 97.41% The model demonstrates excellent specificity, meaning it performs well in identifying the negative class (Alive cases).

AUC (Area Under the Curve): AUC = 0.838. This value reflects the model's strong discriminative ability, indicating that it effectively separates the Alive and Dead classes. Residual Plot:

The residual vs. fitted values plot shows no major pattern, suggesting that the model assumptions hold, and residuals are evenly distributed. ##Conclusion base on the result of validation Model Validation Results: Model 4 performs well in terms of accuracy, specificity, and AUC, supporting its reliability and applicability.

Strengths:

1. Excellent specificity ensures minimal false positives, which is crucial for predictive modeling in sensitive contexts (e.g., survival analysis).

2. Good balance of variables with significant contributions. Weakness:
3. Sensitivity could be improved to reduce false negatives (Dead cases misclassified as Alive).

All in all, this validation confirms that Model 4 is robust and suitable for the given dataset, with opportunities to refine sensitivity if required.
